This paper studies the ideally dissociated gas (air) flow along a porous wall of the body of revolution within the fluid in the conditions of equilibrium dissociation. Using similarity transformations, the governing boundary layer equations are brought to a generalized form. The obtained equations are numerically solved in three-parametric twice localized approximation by finite differences method. Based on the obtained solutions, diagrams of distribution of physical quantities and characteristics of the boundary layer are drawn. General and some specific conclusions about behaviour of these quantities are also made for the studied compressible fluid flow.

Keywords: dissociated gas, boundary layer, porous countour, porosity parameter, fluid mechanics

0 INTRODUCTION

This paper investigates the dissociated gas (air) flow in the boundary layer on bodies of revolution. The contour of the body within the fluid is porous. The dissociated gas flows in the conditions of the so-called equilibrium dissociation [1] and [2].

The goal of our investigations is to apply the general similarity method to the considered flow problem. Naturally, the ultimate objective is to solve the obtained generalized equations in the appropriate approximation.

The general similarity method was first introduced by Loitsianskii [3] and later improved by Saljnikov [4] - Saljnikov's version. Investigators of the Belgrade School used this method to solve many boundary layer flow problems. The most significant results were accomplished in investigations of incompressible fluid flow and with the MHD boundary layer [5]. Solutions for some complicated flow problems [6] were also obtained, (e.g. for the case of the temperature calculating layer on a rotating surface [7]). Both versions of the general similarity method were successfully applied to planar boundary layers with homogenous compressive fluid flow, dissociated and ionized gas flow [8] and [9]. This paper presents the results obtained for the ideally dissociated gas (air) flow along a porous wall of the body of revolution within the fluid in the conditions of equilibrium dissociation. They were obtained using Saljnikov's version of the general similarity method.

1 MATHEMATICAL MODEL

Thermo-chemical equilibrium is assumed to be established in the whole area of the boundary layer. Therefore, a complete equation system for this case of axisymmetrical gas flow in the boundary layer (Fig. 1), with the corresponding boundary conditions [10] and [11], is:

\[
\frac{\partial}{\partial x} (\rho u) + \frac{\partial}{\partial y} (\rho v) = 0,
\]

\[
\rho u \frac{\partial u}{\partial x} + \rho v \frac{\partial u}{\partial y} = \rho \frac{\partial e}{\partial x} + \frac{\partial}{\partial y} \left( \mu \frac{\partial u}{\partial y} \right),
\]

\[
\rho u \frac{\partial h}{\partial x} + \rho v \frac{\partial h}{\partial y} = -u \rho \frac{\partial e}{\partial x} + \mu \left( \frac{\partial u}{\partial y} \right)^2 + \frac{\partial}{\partial y} \left[ \frac{\mu (1 + l)}{Pr} \frac{\partial h}{\partial y} \right],
\]

\[
u = v = v_w(x), \quad h = h_w \quad \text{for} \quad y = 0,
\]

\[
u \to u_e(x), \quad h \to h_e(x) \quad \text{for} \quad y \to \infty.
\]

(1)

In the mathematical model (1), the first equation is a continuity equation of axisymmetrical compressible fluid flow on bodies of revolution, the second one is dynamic, and the third one is energy equation. In the energy equation, the function \(l(p, h)\) for the equilibrium two-componential mixture depends on Lewis number (Le) and on the enthalpy of the atomic \(h_A\) and molecular \(h_M\) components of the equilibrium
dissociated gas (air). This function is determined with the expression [12]

\[ l(p, h) = (Le - l)(h_d - h_M) \left( \frac{\partial C_A}{\partial h} \right)_p \]  

in which \( C_A = \alpha \) stands for the concentration of the atomic component of the ideally dissociated gas.

The radius of the cross-section of the body of revolution, which is normal to axis of revolution, is denoted with \( r(x) \). The contour of the body, which figures in the continuity equation is given by the function \( r(x) \). Therefore, this thickness can be neglected compared to \( r(x) \). However, this assumption cannot be applied to long thin bodies [13].

Unlike other methods [14], the application of the general similarity method involves the usage of the momentum equation and the corresponding sets of similarity parameters. In order to obtain the momentum equation we start from the boundary layer continuity and dynamic equations.

The planar, steady flow of the equilibrium dissociated gas in the boundary layer is determined with the equations system [12] which differs from the system (1) only by the continuity equation. Therefore, for both flow types, the continuity equation can be written in a general form as

\[ \frac{\partial}{\partial x} \left( \rho u r^j \right) + \frac{\partial}{\partial y} \left( \rho v \frac{r}{L} \right) = 0, \]

where \( j = 0 \) for the planar, and \( j = 1 \) for axisymmetrical flow.

It has been shown [15] that a more suitable general form of the continuity equation should be used.

\[ \frac{\partial}{\partial x} \left[ \rho u \left( \frac{r}{L} \right)^j \right] + \frac{\partial}{\partial y} \left[ \rho \frac{v}{L} \left( \frac{r}{L} \right)^j \right] = 0. \]

The equation for axisymmetrical flow (\( j = 1 \)) and \( L = \text{const.} \) reduces to the first equation of the system (1). In the same equation, \( L \) is a characteristic constant length, and for the numerical calculation \( L = 1 \) [16].

2 TRANSFORMATION OF THE GOVERNING BOUNDARY LAYER EQUATIONS

As in already solved flow problems by means of the general similarity method, we introduce variables:

\[ s(x) = \frac{1}{\rho_0 \mu_0} \int_0^x \rho_0 \mu_w \left( \frac{r}{L} \right)^{2j} dx, \]

\[ z(x, y) = \frac{1}{\rho_0} \left( \frac{r}{L} \right)^j \int_0^y \rho \ dy. \]

In the transformations (4) for the new longitudinal \( s(x) \) and transversal \( z(x, y) \) variables, the values \( \rho_0 \) and \( \mu_0 = \rho_0 v_0 \) denote the known values of the density and dynamic viscosity at a
certain point of the boundary layer \((v_0\) is kinematic viscosity). Here, \(\rho_c\) and \(\mu_w\) are given values of these quantities at the inner edge of the boundary layer.

These transformations were also used in the papers \([12]\) for \(j = 0\) and \([16]\) for \(j = 1\), but for the case of a non-porous contour of the body of revolution within the fluid. It should be noted that the transformations \((4)\), due to factors \((r/L)^2\) and \(r/L\) \((j = 1)\), contain Mangler-Stepanov transformations \([11]\).

When the continuity equation \((3)\) is multiplied with the velocity \(u_c(x)\) at the outer edge of the boundary layer, and when the dynamic equation of the system \((1)\) is multiplied with \((r/L)^j\), by the usual procedure \([15]\) we obtain the momentum equation from these equations. Namely, by integration transversally to the boundary layer (from \(y = 0\) to \(y \to \infty\)) and the change of the variables, the momentum equation is obtained:

\[
\frac{dZ^{**}}{ds} = \frac{F_{ot}}{u_c}.
\]  

\((5)\)

While deriving the momentum equation, we defined the conditional displacement thickness \(\Delta^*(s)\), conditional momentum loss thickness \(\Delta^{**}(s)\) and nondimensional friction function \(\zeta(s):\)

\[
\Delta^*(s) = \int_0^\infty \left(\frac{\rho_c}{\rho} - \frac{u}{u_c}\right) dz,
\]

\[
\Delta^{**}(s) = \int_0^\infty \frac{u}{u_c} \left(1 - \frac{u}{u_c}\right) dz,
\]

\[
\zeta(s) = \left[\frac{\partial(u/u_c)}{\partial(z/\Delta^{**})}\right]_{z=0}.
\]  

\((6)\)

The parameter of the form \(f\) is also defined:

\[
f(s) = u_c Z^{**} = f_j(s); \quad Z^{**} = \frac{\Delta^{**2}}{v_0},
\]

\[
(u_c' = du_c/ ds).
\]  

\((7)\)

The characteristic boundary layer function \(F_{ot}\) in the momentum equation \((5)\) is determined with the expression

\[
F_{ot} = 2 \left[ \zeta - (2 + H) f \right] + \frac{2}{(r/L)^j} \frac{v_w \Delta^{**}}{v_0} \frac{\mu_0}{\mu_w},
\]

\[
H = \frac{\Delta^*}{\Delta^{**}}.
\]  

\((8)\)

where the subscript \(ot\) denotes the body of revolution.

For the case of a non-porous wall of the body within the fluid (for which \(v_w = 0\) the expression for the characteristic function \(F_{ot}\) comes down to the expression for the function \(F\) \((F_{ot} = F)\) of the planar dissociated gas flow \([12]\). In this case, the expression for this function is formally the same as the one for incompressible fluid flow \([3]\). For \(j = 0\) this function is completely the same as the function \(F_{dp}\) for the planar dissociated gas flow \([17]\).

Based on the relations \((8)\) for \(F_{ot}\), the porosity parameter \(\Lambda(s)\) can be defined as:

\[
\Lambda(s) = - \frac{l}{(r/L)^j} \frac{\mu_0}{\mu_w} \frac{v_w \Delta^{**}}{v_0} = -v_w \frac{\Delta^{**}}{v_0} = \Lambda_j(s),
\]

\[
V_w = \frac{l}{(r/L)^j} \frac{\mu_0}{\mu_w} v_w \quad (j = I),
\]  

\((9)\)

where \(V_w(s)\) represents the conditional fluid injection velocity. Therefore, the function \(F_{ot}\) of the boundary layer can be written in the form of

\[
F_{ot} = 2 \left[ \zeta - (2 + H) f \right] - 2\Lambda
\]  

\((10)\)

and as such it will be used hereafter. It should be noted that because of the relationship between the quantities \(Z^{**}, \Delta^{**}\) and \(f\) the momentum equation \((5)\) can be written in two other forms \([17]\).

In order to solve the governing equation system, we introduce a stream function \(\psi(s, z)\):

\[
u = \frac{\partial \psi}{\partial z},
\]

\[
v = \frac{l}{(r/L)^j} \frac{\rho_0}{\rho_w} \mu_0 \left[\frac{\partial z}{\partial \psi} + \left(\frac{r}{L}\right)^j \frac{\rho}{\rho_0}\right] = \frac{\partial \psi}{\partial s} \quad (j = I)
\]  

\((11)\)

in accordance with the relations that result from the continuity equation \((3)\). For \(j = 0\) these relations come down to the expressions used in the paper \([12]\).
Applying transformations (4) and the stream function (11), the governing system takes the following form:

\[
\frac{\partial \psi}{\partial z} \frac{\partial^2 \psi}{\partial s^2} - \frac{\partial \psi}{\partial s} \frac{\partial^2 \psi}{\partial s \partial z} = \frac{\rho_e}{\rho} u_e \frac{du_e}{ds} + v_0 \frac{\partial}{\partial z} \left( Q \frac{\partial^2 \psi}{\partial z^2} \right),
\]

\[
\frac{\partial \psi}{\partial z} \frac{\partial h}{\partial s} \left( \frac{\partial \psi}{\partial s} \frac{\partial h}{\partial z} \right) = -\frac{\rho_e}{\rho} u_e \frac{du_e}{ds} \frac{\partial \psi}{\partial s} + v_0 \frac{\partial}{\partial z} \left[ Q \frac{\partial^2 \psi}{\partial z^2} \right] + v_0 \frac{\partial}{\partial z} \left[ Q \frac{h}{Pr} (1 + l) \frac{\partial h}{\partial z} \right].
\]

\[
\frac{\partial \psi}{\partial z} = 0, \quad \frac{\partial \psi}{\partial s} = -\frac{1}{(r/L)^j} \mu \frac{\partial \psi}{\partial s} = -V_w, \quad h = h_w \text{ for } z = 0,
\]

\[
\frac{\partial \psi}{\partial z} \rightarrow u_e(s), \quad h \rightarrow h_v(s) \text{ for } z \rightarrow \infty. \tag{12}
\]

In the equation system (12), the nondimensional function \( Q \) is determined with the expression:

\[
Q = \frac{\rho \mu}{\rho_w \mu_w}; \quad Q = 1 \text{ for } z = 0,
\]

\[
Q = \frac{\rho_e u_e}{\rho_w \mu_w} = Q(s) \text{ for } z \rightarrow \infty. \tag{13}
\]

For further application of the general similarity method, the stream function \( \psi(s, z) \) should be divided into two parts:

\[
\psi(s, z) = \psi_w(s) + \varphi(s, z), \quad \varphi(s, 0) = 0. \tag{14}
\]

Here, \( \psi_w(s) = \psi(s, 0) \) denotes the stream function along the wall of the body within the fluid \( (z=0) \), and \( \varphi(s, z) \) is now a new stream function.

Applying the relations (14), the equation system (12) is easily transformed into:

\[
\frac{\partial \varphi}{\partial z} \frac{\partial^2 \varphi}{\partial s^2} - \frac{\partial \varphi}{\partial s} \frac{\partial^2 \varphi}{\partial s \partial z} = \frac{\rho_e}{\rho} u_e \frac{du_e}{ds} + v_0 \frac{\partial}{\partial z} \left( Q \frac{\partial^2 \varphi}{\partial z^2} \right),
\]

\[
\frac{\partial \varphi}{\partial z} \frac{\partial h}{\partial s} \left( \frac{\partial \varphi}{\partial s} \frac{\partial h}{\partial z} \right) = -\frac{\rho_e}{\rho} u_e \frac{du_e}{ds} \frac{\partial \varphi}{\partial s} + v_0 \frac{\partial}{\partial z} \left[ Q \frac{\partial^2 \varphi}{\partial z^2} \right] + v_0 \frac{\partial}{\partial z} \left[ Q \frac{h}{Pr} (1 + l) \frac{\partial h}{\partial z} \right].
\]

\[
\varphi(s, z) = 0, \quad \frac{\partial \varphi}{\partial s} = 0, \quad h = h_w \text{ for } z = 0,
\]

\[
\frac{\partial \varphi}{\partial z} \rightarrow u_e(s), \quad h \rightarrow h_v(s) \text{ for } z \rightarrow \infty. \tag{15}
\]

Unlike the system (12), both equations of the system (15) contain a new term in which the derivative \( d\psi_w/ds \) appears. This derivative is determined with:

\[
d\psi_w/ds = \left( \frac{\partial \psi}{\partial s} \right)_{z=0} = -\frac{1}{(r/L)^j} \mu \frac{\partial \psi}{\partial s} = -V_w, \quad (j = l). \tag{16}
\]

The expression (16) for the derivative \( d\psi_w/ds \) for \( j = 0 \) comes down to the corresponding expression for the planar dissociated gas flow [17]. In the case of a nonporous wall of the body within the fluid, this derivative equals zero. Then, the terms in the equations (15) equal zero. In this case, the obtained equation system is completely identical with the one obtained in the paper [12] for the planar flow along a nonporous wall.

3 GENERALIZED BOUNDARY LAYER EQUATIONS ON BODIES OF REVOLUTION

For the application of the general similarity method, we used the procedure already used for both, incompressible and compressible fluid in [4]. We introduced new changes of the variables:

\[
s = s, \quad \eta(s, z) = \frac{u_e^{b/2}}{S(s)} z, \quad S(s) = \left( \int_0^s u_e^{b-1} ds \right)^{1/2}, \quad a, b = \text{const};
\]

\[
\varphi(s, z) = u_e^{-b/2} S(s) \phi(s, \eta), \quad h(s, z) = h_1 \cdot h(s, \eta); \quad h_1 = \text{const}. \tag{17}
\]
Table 1. List of variables

</tbody>
</table>

In expression (17), \( \eta(s, z) \) is a newly introduced variable, \( \Phi(s, \eta) \) is a new stream function, while \( \overline{h} \) is a nondimensional enthalpy. Here, \( h_1 \) denotes the enthalpy at the front stagnation point of the body within the fluid. Table 1 gives a list of the starting and the newly introduced variables.

Based on the variables (17), the important quantities and characteristics of the boundary layer (e.g. (6)) can be expressed in the form of:

\[
\frac{u}{u_e} = \frac{\partial \Phi}{\partial \eta}, \quad \Delta^{**}(s) = \frac{S(s)}{u_e h_1^2} B(s),
\]

\[
\frac{\Delta^*}{\Delta^{**}} = H = \frac{A}{B}, \quad \zeta = B \left( \frac{\partial^2 \Phi}{\partial \eta^2} \right)_{\eta=0},
\]

\[
A(s) = \int_0^\infty \left( \frac{\rho - \frac{\partial \Phi}{\partial \eta} }{\partial \eta} \right) d\eta,
\]

\[
B(s) = \int_0^\infty \frac{\partial \Phi}{\partial \eta} \left( 1 - \frac{\partial \Phi}{\partial \eta} \right) d\eta.
\]

The transversal variable and the stream function can also be written in a more suitable form as:

\[
\eta(s, z) = \frac{B(s)}{\Delta^{**}(s)} z,
\]

\[
\overline{\psi}(s, z) = \frac{u_e(s) \Delta^{**}(s)}{B(s)} \Phi(s, \eta).
\]

After the calculation of the derivatives and after comprehensive transformations, the equation system (15) reduces to the form that is not generalized according to the general similarity method. Thus transformed dynamic and energy equations contain the factor \( u_e / u_e' \) in their terms. Therefore, the solution of the system will depend on the concrete form of the law of the given velocity at the outer edge of the boundary layer \( u_e(s) \).

In order to bring the equation system (15) to a generalized form, it is necessary to introduce the transformations (17) and (19) and the corresponding sets of parameters. For application of Saljnikov’s version of the general similarity method, we introduce a new stream function \( \Phi \) and a new nondimensional enthalpy \( \overline{h} \):

\[
\overline{\psi}(s, z) = \frac{u_e A^{**}}{B} \cdot \Phi[\eta, \kappa, (f_k), (A_k)],
\]

\[
h(s, z) = h_1 \cdot \overline{h} [\eta, \kappa, (f_k), (A_k)],
\]

where \( \kappa \) is the local compressibility parameter [12].

In the generalized similarity transformations (20), with the newly introduced functions \( \Phi \) and \( \overline{h} \), the set of parameters of the form \( f_k(s) \) of Loitsianskii type [3] and the set of parameters \( A_k(s) \) of the porous wall [15] are defined as:

\[
f_0(s) = \kappa = u_e^2 / 2 h_1, \quad f_k(s) = u_e^{k-1} u_e^{(k)} Z^{**},
\]

\[
A_k(s) = -u_e^{k-1} \left( \frac{V_w}{\sqrt{\nu_0}} \right)^{(k-1)} Z^{**/k-2},
\]

\[
h_e + u_e^2 / 2 = h_1, \quad \overline{h}_e = h_e / h_1, \quad \overline{h}_k(s) = 1 - \kappa, \quad k = 1, 2, 3, ...
\]

The introduced sets of parameters reflect the conditions of the outer flow, and in the transformations (20), they represent independent variables (instead of the variable \( s \)). Both sets of parameters (21) satisfy the corresponding recurrent simple differential equations:

\[
\frac{u_e f}{u_e'} \frac{d\kappa}{ds} = 2 \kappa f = 2 \kappa f_1 = \theta_0,
\]

\[
\frac{u_e f}{u_e'} \frac{df_k}{ds} = [(k-1)f_1 + k F_{ad}] f_k + f_{k+1} = \theta_k
\]
\[ \frac{u_e}{f_1} \frac{dA_k}{ds} = \left\{ (k - 1)f_1 + \left[ \frac{(2k - 1)}{2} \right] F_{\rho} \right\} A_k + A_{k+1} = \chi_k. \]  

(22)

These equations are formally the same as the ones for the case of incompressible fluid flow [3]. Furthermore, from (21) for \( k=1 \) it follows that \( f_1(s) = u_e Z^* \) is the already known parameter of the form (7), while from the set of the porosity parameters for the first parameter we get the expression

\[ A_1 = -\frac{V_w}{\sqrt{V_0}} Z^{*1/2} = -\frac{V_w}{\sqrt{V_0}} \frac{A^{**}}{V_0} = \frac{V_w A^{**}}{V_0}, \]

which is the same as the previously defined parameter (9).

Applying (17) and (20), the equation system (15) is brought to a generalized equation system of the dissociated gas boundary layer:

\[ \frac{\partial}{\partial \eta} \left( \frac{Q}{\partial^2 \Phi} \right) + \frac{aB^2 + (2-b)f_1}{2B^2} \Phi \frac{\partial^2 \Phi}{\partial \eta^2} + \frac{f_1}{B^2} \left[ \frac{\rho_e}{\rho} \left( \frac{\partial \Phi}{\partial \eta} \right)^2 \right] + \frac{A_1}{B} \frac{\partial^2 \Phi}{\partial \eta^2} = \]

\[ = \frac{1}{B^2} \left[ \sum_{k=0}^{\infty} \theta_k \left( \frac{\partial \Phi}{\partial \eta} \frac{\partial f_k}{\partial \eta} - \frac{\partial \Phi}{\partial \eta} \frac{\partial f_k}{\partial \eta} \right) + \sum_{k=1}^{\infty} \chi_k \left( \frac{\partial \Phi}{\partial \eta} \frac{\partial f_k}{\partial \eta} - \frac{\partial \Phi}{\partial \eta} \frac{\partial f_k}{\partial \eta} \right) \right], \]

\[ \frac{\partial}{\partial \eta} \left( \frac{Q}{Pr (1+l) \frac{\partial h}{\partial \eta}} \right) + 2f_1 \left[ \frac{\rho_e}{\rho} \left( \frac{\partial \Phi}{\partial \eta} \right)^2 \right] + \frac{A_1}{B} \frac{\partial h}{\partial \eta} = \]

\[ = \frac{1}{B^2} \left[ \sum_{k=0}^{\infty} \theta_k \left( \frac{\partial \Phi}{\partial \eta} \frac{\partial h}{\partial \eta} - \frac{\partial \Phi}{\partial \eta} \frac{\partial h}{\partial \eta} \right) + \sum_{k=1}^{\infty} \chi_k \left( \frac{\partial \Phi}{\partial \eta} \frac{\partial h}{\partial \eta} - \frac{\partial \Phi}{\partial \eta} \frac{\partial h}{\partial \eta} \right) \right]; \]

\[ \Phi = 0, \frac{\partial \Phi}{\partial \eta} = 0, \frac{\partial h}{\partial \eta} \to \frac{h}{\eta} = const. \text{ for } \eta \to 0, \frac{\partial \Phi}{\partial \eta} \to 1, \frac{h}{\eta} \to \frac{h}{\eta} (s) = 1 - \kappa \text{ for } \eta \to \infty. \]  

(23)

The system of generalized equations (23) has the same form as the system [17] for planar flow of dissociated gas along a porous contour. For \( j=0 \) these systems are completely identical because in that case the expressions for porosity parameters are also identical. For the case of a nonporous wall \( (v_w = 0 \Rightarrow V_w = 0, \Lambda_1 = 0) \), the equations (23) formally come down to the corresponding equations obtained in the paper [12].

The equation system (23) is solved in the so-called n-parametric approximation. In three-parametric twice localized approximation \( (f_0 = \kappa = 0, f_1 = f_0, \Lambda_1 = \Lambda = 0, f_k = 0, \Lambda_k = 0) \) for \( k \geq 2 \) and \( \partial^2 / \partial \kappa \approx 0, \partial / \partial \Lambda \approx 0 \) this system has the following form:

\[ \frac{\partial}{\partial \eta} \left( \frac{Q}{\partial^2 \Phi} \right) + \frac{aB^2 + (2-b)f_1}{2B^2} \Phi \frac{\partial^2 \Phi}{\partial \eta^2} + \frac{f_1}{B^2} \left[ \frac{\rho_e}{\rho} \left( \frac{\partial \Phi}{\partial \eta} \right)^2 \right] + \frac{A_1}{B} \frac{\partial \Phi}{\partial \eta} = \]

\[ = \frac{F_{\rho f_1}}{B^2} \left[ \frac{\partial \Phi}{\partial \eta} \frac{\partial \Phi}{\partial \eta} - \frac{\partial \Phi}{\partial \eta} \frac{\partial \Phi}{\partial \eta} \right], \]

\[ \frac{\partial}{\partial \eta} \left( \frac{Q}{Pr (1+l) \frac{\partial h}{\partial \eta}} \right) + \frac{aB^2 + (2-b)f_1}{2B^2} \Phi \frac{\partial h}{\partial \eta} - 2f_1 \left[ \frac{\rho_e}{\rho} \left( \frac{\partial \Phi}{\partial \eta} \right)^2 \right] + 2\kappa Q \left( \frac{\partial^2 \Phi}{\partial \eta^2} \right)^2 + \frac{A_1}{B} \frac{\partial h}{\partial \eta} = \]

\[ = \frac{F_{\rho f_1}}{B^2} \left[ \frac{\partial \Phi}{\partial \eta} \frac{\partial h}{\partial \eta} - \frac{\partial \Phi}{\partial \eta} \frac{\partial h}{\partial \eta} \right]; \]

\[ \Phi = 0, \frac{\partial \Phi}{\partial \eta} = 0, \frac{\partial h}{\partial \eta} \to \frac{h}{\eta} = \frac{h}{\eta} \text{ const. for } \eta \to 0, \frac{\partial \Phi}{\partial \eta} \to 1, \frac{h}{\eta} \to \frac{h}{\eta} (s) = 1 - \kappa \text{ for } \eta \to \infty. \]  

(24)
dissociated gas (air) flow in the boundary layer along a body of revolution under the conditions of equilibrium dissociation. The terms that contain the porosity parameter \( \Lambda_1 \) are characteristic for the porous wall of the body of revolution. The equation system (24) is of the same form as the corresponding system for the planar flow problems [17].

For a numerical solution of the obtained equation system, the order of the dynamic equation is decreased:

\[
\frac{u}{u_e} = \frac{\partial \Phi}{\partial \eta} = \frac{\varphi(\eta, \kappa, f_i, \Lambda_1)}{\varphi(\kappa, f_i, \Lambda_1)}.
\]  
(25)

Then, based on the results stated in [12], for the equilibrium dissociated air it is accepted that \( \text{Le} = 1 \), and consequently \( f_i = 0 \). According to the same author, the function \( Q \) (13) and the density ratio \( \rho_e / \rho \), that figure in the equation system (24), can be expressed using the formulae:

\[
Q = Q(\tilde{h}) = \left( \frac{\tilde{h}}{h} \right)^{\frac{3}{2}}, \quad \frac{\rho_e}{\rho} \approx \frac{\tilde{h}}{1 - \kappa}.
\]  
(26)

The formula for the function \( Q \) gives satisfactory results for a wide range of the pressure change. The formula for the density ratio that follows from the corresponding formulae stated in [12], gives a rather rough approximation.

Taking (25) and (26) into consideration, we come to a generalized equation system with four independent variables: \( \eta, \kappa, f_i \) and \( \Lambda_1 \):

\[
\begin{align*}
\frac{\partial}{\partial \eta} \left[ Q \frac{\partial \varphi}{\partial \eta} \right] + \frac{aB^2 + (2 - b)f_i}{2B^2} \Phi \frac{\partial \varphi}{\partial \eta} + \\
+ \frac{f_e}{B^2} \left[ \frac{\tilde{h}}{1 - \kappa} - \varphi^2 \right] + \Lambda_1 \frac{\varphi}{B} \frac{\partial \Phi}{\partial \eta} = \\
= \frac{F_\alpha f_i}{B^2} \left[ \Phi \frac{\partial \varphi}{\partial f_i} - \frac{\partial \Phi}{\partial f_i} \frac{\partial \varphi}{\partial \eta} \right],
\end{align*}
\]

\[
\begin{align*}
\frac{\partial}{\partial \eta} \left[ Q \frac{\partial \tilde{h}}{\partial \eta} \right] + \frac{aB^2 + (2 - b)f_i}{2B^2} \Phi \frac{\partial \tilde{h}}{\partial \eta} - \\
- \frac{2 \kappa f_i}{B^2} \varphi \left[ \frac{\tilde{h}}{1 - \kappa} - \varphi^2 \right] + 2 \kappa Q \left( \frac{\partial \varphi}{\partial \eta} \right)^2 + \\
+ \frac{\Lambda_1}{B} \frac{\partial \tilde{h}}{\partial \eta} = \frac{F_\alpha f_i}{B^2} \left[ \Phi \frac{\partial \tilde{h}}{\partial f_i} - \frac{\partial \Phi}{\partial f_i} \frac{\partial \tilde{h}}{\partial \eta} \right],
\end{align*}
\]

\[
\Phi = 0, \quad \varphi = 0, \quad \tilde{h} = \tilde{h}_w = \text{const. for } \eta = 0,
\]

\[
\varphi \to 1, \quad \tilde{h} \to \tilde{h}_c = 1 - \kappa \text{ for } \eta \to \infty.
\]  
(27)

4 NUMERICAL SOLUTION

Numerical solution of the obtained system of partial differential equations (27) is performed by the passage method, i.e., by the finite difference method. Here, the whole area of the boundary layer is changed with the planar integration grid with spaces \( \Delta f_i \) and \( \Delta \eta \) [4]. Some derivatives in the equations (27) are changed with the corresponding finite differences of the functions at discrete points of the grid: \((M, K), (M - 1, K + 1), (M, K + 1), (M + 1, K + 1)\).

The values of the functions \( \varphi, \Phi \) and \( \tilde{h} \) are calculated at discrete points of each calculating layer \((K + 1)\). Because of the complexity of the considered flow problem, the number of discrete points from \( M = 1 \) to \( M = N = 401 \) has been determined for each layer calculating.

For the numerical solution of the generalized equation system (27), i.e., of the corresponding equivalent system, a program in FORTRAN programming language has been written. This program was used in our paper [17], and is based on the one used in the paper [4]. The equations are solved for the following values of the parameters and coefficients: \( \text{Pr} = 0.712; \quad a = 0.4408, \quad b = 5.714 \) [4]. For the characteristic functions \( B \) and \( F_\alpha \) at a zero iteration, the following values are accepted: \( B^0_{K+1} = 0.449 \) and \( F^0_{\alpha, K+1} = 0.44411 \). They were also used in the investigations [4].

5 THE OBTAINED RESULTS

Numerical solutions of the generalized equations (27) are first obtained for each cross-section of the boundary layer in the form of tables. Then, based on the tables, diagrams of the nondimensional velocity, nondimensional enthalpy and characteristic quantities of the boundary layer are drawn. Again, note that due to transformations (4), the obtained generalized equations (27) are formally the same as the ones obtained in [17].

This paper gives only some of the most important diagrams obtained in the course of our investigations. Figure 2 is the diagram of the nondimensional velocity \( u/u_e \) for three cross-sections of the boundary layer. Figure 3 shows
Fig. 2. Diagram of the nondimensional velocity $u/u_e$

Fig. 3. Diagram of the nondimensional enthalpy $\bar{h}$

Fig. 4. Diagram of the nondimensional enthalpy $\bar{h}$ for different values of the parameter $f_0$

Fig. 5. Distribution of the nondimensional friction function $\zeta(f)$

The diagram of the nondimensional enthalpy $\bar{h}$ also at three cross-sections of the boundary layer when the compressibility parameter is $\kappa = f_0 = 0.5$. The diagrams on Fig. 4 represent the distribution of the nondimensional enthalpy for different values of the compressibility parameter. Finally, Fig. 5 shows the distribution of the nondimensional friction function $\zeta(f)$. Here, the subscript 1 in the parameter of the form $(f_1 = f_1)$ is left out.

6 CONCLUSIONS

The paper shows that the general similarity method can be applied in the studied case of the fluid flow. However, the application of this method to the problem of the ideally dissociated gas (air) flow in the boundary layer on bodies of revolution is associated with some complexities, which are primarily of mathematical nature. There are also some problems related to physical, i.e., thermochemical processes of gas flow (e.g. (26)). Nevertheless, we have obtained some important quality results that give us an insight into the behaviour of the distribution of physical and characteristic quantities at different cross-sections of the boundary layer.

It should be noted that the porosity parameter $\Lambda(s)$ (9) and a set of parameters $\Lambda_\epsilon(s)$ of the porous wall of the body of revolution (21), enabled the application of the general similarity method to this problem.
It is specifically pointed out that the system of generalized equations (23) has the same form as the corresponding system for planar flow of dissociated gas along a porous contour. But this is quite expected and it is due to the transformations (4) that contain the terms \((r/L)^2\) and \(r/L\).

Based on the numerical results, i.e., on the presented and other diagrams, a general conclusion can be drawn: distributions of the solutions of the obtained boundary layer equations are of the same behaviour as with other dissociated gas flow problems.

For the considered case, the following concrete conclusions can be drawn:

- The nondimensional flow velocity \(u/u_e = \partial \Phi/\partial \eta\) at different cross-sections of the boundary layer on the body of revolution (different \(f\)) converges very fast towards unity (Fig. 2).
- The influence of the compressibility parameter \(\kappa = f_0\) on the distribution of the nondimensional enthalpy at the cross-section of the boundary layer is considerable (Fig. 4). This is due to the fact that the value of the nondimensional enthalpy is determined with this parameter at the outer edge of the boundary layer \((\bar{\eta} = \bar{\eta}_e = 1 - \kappa)\) for \(\eta \to \infty\).
- In order to obtain results that are more reliable, it is necessary to solve the system (23) in three-parametric approximation but without the localization per corresponding parameters. It is important that the solutions should be obtained without localization per the compressibility parameter. This parameter has a great influence on the change of the enthalpy in the boundary layer, and it even changes the general character of behaviour of the distribution of enthalpy. However, this solution would involve even more complexities of mathematical nature.
- From the diagrams in Figure 5 and others not shown here, it is obvious that the porosity parameter has a considerable influence on all the important characteristics of the boundary layer. This parameter influences the nondimensional friction function \(\zeta\), and, consequently, it influences the boundary layer separation point.

We should also note that there were some problems in numerical solution of the system (24). Namely, the program stopped working for some input values. This was the problem encountered in other cases of the boundary layer flow, as pointed out by some authors [7].

7 ACKNOWLEDGEMENT

This paper is the result of investigations carried out within the scientific project ON144022 supported by the Ministry of Science and Environmental Protection of the Republic of Serbia.

8 REFERENCES

Navodila avtorjem

Članki morajo vsebovati:
- naslov, povzetek, ključne besede,
- besedilo članka,
- preglednice in slike (diagrami, risbe ali fotografije) s podnaslovom,
- seznam literature in
- podatke o avtorjih, odgovornem avtorju in njegov polni naslov.

Članki naj bodo kratki in naj obsejajo približno 8-12 strani.

Člankom so lahko priložene tudi dodatne računalniške simulacije ali predstavitve, pripravljene v primerni obliki, ki bodo bralcem dostopne na spletni strani revije.

VSEBINA ČLANKA

Članek naj bo napisan v naslednji obliki:
- Naslov, ki primerno opisuje vsebino članka.
- Povzetek, ki naj bo skrajšana oblika članka in naj ne presega 250 besed. Povzetek mora vsebovati osnove, jedro in cilje raziskave, uporabljeno metodologijo dela, povzetek rezultatov in osnovne sklepe.
- Uvod, v katerem naj bo pregled novejsega stanja in zadostne informacije za razumevanje ter pregled rezultatov dela, predstavljenih v članku.
- Teorija.
- Eksperimentalni del, ki naj vsebuje podatke o postavitvi preskuša in metode, uporabljene pri pridobitvi rezultatov.
- Rezultati, ki naj bodo jasno prikazani, po potrebi v obliki slik in preglednic.
- Razprava, v kateri naj bodo prikazane povezave in pospešitve, uporabljene za pridobitev rezultatov. Prikazana naj bo tudi pomembnost rezultatov in primerjava s poprej objavljenimi deli. (Zaradi narave posameznih raziskav so lahko rezultati in razprava, za jasnost in preprostješje braščave razumevanje, združeni v ene poglavje.)
- Sklepi, v katerih naj bo prikazan en ali več skleпов, ki izhajajo iz rezultatov in razprave.
- Literatura, ki mora biti v besedilu oštevilčena zaporedno in označena z oglatimi oklepaji [1] ter na koncu članka zbrana v seznamu literature.

OBLIKA ČLANKA

Besedilo članka naj bo pripravljeno v urejevalniku Microsoft Word. Članek nam dostavite v elektronski obliki (lahko po elektronski pošti). Ne uporablajte urejevalnika LaTeX, saj program, s katerim pripravljamo Strojniški vestnik, ne uporablja njegovega formatn. Enačbe naj bodo v besedilu postavljene v ločene vrstice in na česem robu označene s tekočo številko v okroglih oklepaji.

Enote in okrajšave

V besedilu, preglednicah in slikah uporabljajte le standardne označbe in okrajšave SI. Simbole fizičnih veličin v besedilu pišite poševno (kurzivno), (npr. v, T, n itn.). Simbole enot, ki sestojijo iz črk, pa ponučno (npr. m s⁻¹, K, min, mm itn.). Vse okrajšave naj bodo, ko se prvič pojavijo, napisane v celoti, npr časovno spremenljiva geometrija (ČSG). Vse veličine morajo biti navedene, ko se prvič pojavijo, v besedilu ali za enačbo.

Slike

Slike morajo biti zaporedno oštevilčene in označene, v besedilu in podnaslovu, kot sl. 1, sl. 2 itn. Posnetek naj bodo v ločljivosti, primerni za štisk, v katerekoli od razširjenih formatov, npr. BMP, JPG, GIF. Diagrami in risbe morajo biti pripravljeni v vektorskem formatu, npr. CDR, AI.

Vse slike morajo biti pripravljene v črno-belih tehniki, brez robk ob okoli slik in na beli podlagi. Loceno pošljite vse slike v izvini obliki.
Pri označevanju oz. v diagramih, kadar je le mogoče, uporabite označbe veličin (npr. t, v, m itn.). V diagramih z več krivuljami, mora biti vsaka krivulja označena. Pomen označ mora biti pojasnjen v podnapisu slike.

Preglednice

Preglednice morajo biti zaporedno oštevilčene in označene, v besedilu in podnaslovu, kot preglednica 1, preglednica 2 ita. K fizikalnim veličinam, npr. t (pisano posebno), pripišite enote (pisano pokončno) v oglatih oklepajih.

Seznam literature

Vsā literatura mora biti navedena v seznamu na koncu članka v prikazani obliki po vrsti za revije, zbornike in knjige:

SPREJEM ČLANKOV IN AVTORSKE PRAVICE

Uredništvo Strojniškega vestnika si pridržuje pravico do odločanja o sprejemu članka za objavo, strokovno oceno recenzentov in morebitnem predlogu za krajšanje ali izpopolnitve ter terminološke Korekture.

Avtor mora predložiti pisno izjavo, da je besedilo njegovo izvorno delo in ni bilo v časni obliki še nikjer objavljeno. Z objavo preidejo avtorske pravice na Strojniški vestnik. Pri morebitnih kasnejših objavah mora biti SV naveden kot vir.

Avtorji lahko spremljajo stanje svojih sprejetih člankov na spletni strani revije: http://en.sv-jme.eu/.

Plačilo objave

Avtorji vseh prispjekov morajo za objavo plačati prispevek v višini 180,00 EUR (za članek dolžine do 6 strani), 220,00 EUR (za članek dolžine do 10 strani) ter 26,00 EUR za vsako dodatno stran. Prispevek se zaračuna po sprejemu članka za objavo na seji Uredniškega odbora.
